EXPERIMENT-12

Implementing Security Features and Governance / Administration Practices in Zoho Creator

Aim:

To implement security features and governance practices in the Zoho Creator Insurance Claim application by configuring user roles, permission sets, data-sharing rules, role hierarchy, and access permissions to ensure secure access to application data.

Overview:

Security and governance are important aspects of application development because they protect sensitive information and ensure that users can access only the data and functionalities required for their responsibilities.

Zoho Creator provides security features such as role-based access control (RBAC), permission sets, data-sharing rules, and role hierarchy to manage users and control access to application resources.

In the Insurance Claim application, different roles such as CEO, Administrator, Insurance Agent, and Customer can be configured according to their responsibilities. Permission sets define the operations users can perform, such as viewing, adding, editing, or deleting records. Data-sharing rules control which records are accessible to particular users, while role hierarchy determines how access can be inherited between roles.

Administrative practices include reviewing user access, assigning appropriate permissions, testing access restrictions, and maintaining application security. These practices help protect customer details, insurance policies, and claim records from unauthorized access.

Algorithm:

1. **Open Zoho Creator:** Log in to Zoho Creator and open the existing Insurance Claim application in the application builder.

2. **Access user management:** Navigate to the Users and Permissions or application settings section to manage roles and user access.

3. **Create user roles:** Create or verify the roles CEO, Administrator, Insurance Agent, and Customer according to the responsibilities of each user.

4. **Configure permission sets:** Create or verify the permission sets `Insurance_Agent_Permissions` and `Customer_Permissions`.

5. **Assign permissions:** Configure the permissions required for each role, including access to forms, reports, and records.

6. **Configure data-sharing rules:** Create or review data-sharing rules to control access to Customer Details, Insurance Policy, and Insurance Claim records.

7. **Configure role hierarchy:** Enable or review the role hierarchy for the relevant forms so that record access follows the configured organizational structure.

8. **Assign users to roles:** Associate application users with the appropriate roles and permission sets.

9. **Restrict unauthorized access:** Ensure that users cannot view or modify records beyond the permissions granted to them.

10. **Test user access:** Log in or use authorized test accounts to verify that each role can access only the permitted application features and records.

11. **Verify application security:** Check that customer information, policy details, and claim records are protected according to the configured access rules.

12. **Review administration settings:** Verify user assignments, permissions, and sharing rules to maintain consistent application governance.

13. **Document the configuration:** Record the roles, permission sets, sharing rules, and access tests performed in the application.

Result:

Thus, security features and governance practices were implemented and configured in the Zoho Creator Insurance Claim application using role-based access control, permission sets, data-sharing rules, and role hierarchy. User access was organized according to assigned responsibilities to support secure data access and effective application administration.
